Abstract

The rates of hypertension in Kenya are high due to low levels of awareness and treatment. To combat this, blood pressure cuffs will be distributed to local hospitals. Five years after implementation, incidences of hypertension will decrease as education leads to lifestyle changes.

Background

• Hypertension affects 12.3% of Nairobi slum dwellers and 20% are aware of their condition
• Area has poor healthcare with 11.8 nurses per 10,000 people
• Inexpensive treatment can be implemented involving education, monitoring and lifestyle changes

Methods/Process

• Submit applications for grants to foundations to obtain project funds
• Distribution of BP Boxes including educational pamphlets and electronic blood pressure cuffs.
• Population includes community members living around hospitals in Viwandani

Results/Outcomes

• Incidence rate decreased from 12.3% to 8%
• Percentage of population aware of hypertension, increased from 20% to 70%

Acknowledgements

We would like to thank Tom Hohenstein, the research specialist, for his guidance.

Conclusions/Recommendations

Lifestyle changes and consistent monitoring have a positive correlation with low blood pressure. This method has potential to be successful in other slums.
