A new microwave imaging technique is proposed for reconstruction of two-dimensional complex permittivity profiles in dielectric samples located in a waveguide system. The spatial distributions of the dielectric constant and the loss factor are approximated by continuous functions whose functional parameters are determined using a neural network technique backed by full-wave finite-difference time-domain analysis. The profiles are reconstructed from measurements of reflection and transmission characteristics obtained with the tested sample at different locations. Operational capabilities of the technique are illustrated through a series of computational experiments for rectangular and cylindrical samples at two (original and 90°-rotated) positions. The results demonstrate excellent agreement between the reconstructed and actual profiles approximated by linear (Fig. 1a), quadratic (Fig. 1b) and Gaussian functions (Fig. 1c-e): the average relative errors do not exceed 0.4, 2.2, and 4.8%, respectively.
